class13

Kai Zhao(PID:A17599942)

Today we will examine RNASeq data from a published RNA-seq experiment where airway smooth muscle cells were treated with dexamethasone, a synthetic glucocorticoid steroid with anti-inflammatory effects (Himes et al. 2014).

```
#Complete the missing code

```

```
#apply(control.counts, 1, mean)
```

> Q3. How would you make the above code in either approach more robust

```
control.mean<- rowMeans(control.counts)
```

Now the same steps to get "treated.mean"

Q4. Follow the same procedure for the treated samples (i.e. calculate the mean per gene across drug treated samples and assign to a labeled vector called treated.mean)

```
treated.inds <- metadata$dex =="treated"
```

```
metadata[treated.inds,]
```

```
          id     dex celltype     geo_id
2 SRR1039509 treated   N61311 GSM1275863
4 SRR1039513 treated  N052611 GSM1275867
6 SRR1039517 treated  N080611 GSM1275871
8 SRR1039521 treated  N061011 GSM1275875
```

```
treated.counts <- counts[, treated.inds]
head(treated.counts)
```

```
                SRR1039509 SRR1039513 SRR1039517 SRR1039521
ENSG00000000003        486        445       1097        604
ENSG00000000005          0          0          0          0
ENSG00000000419        523        371        781        509
ENSG00000000457        258        237        447        324
ENSG00000000460         81         66         94         74
ENSG00000000938          0          0          0          0
```

```
treated.mean <- rowMeans( counts[, metadata$dex == "treated"])
```

To keep us tidy lets put 'control.mean' and 'treated.mean' vectors together as two columns of a new data.frame.

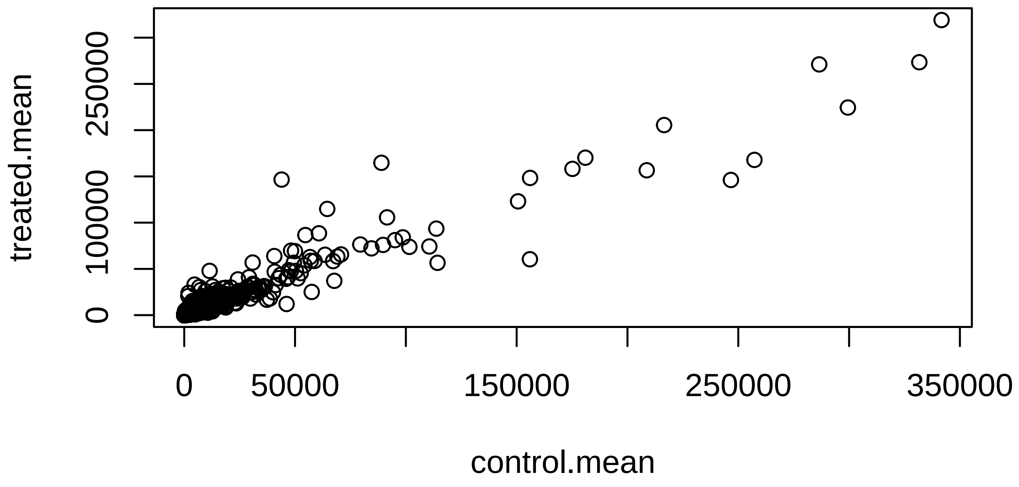
```
meancounts <- data.frame(control.mean, treated.mean)
```

```
head(meancounts)
```

```
                control.mean treated.mean
ENSG00000000003       900.75       658.00
ENSG00000000005         0.00         0.00
ENSG00000000419       520.50       546.00
ENSG00000000457       339.75       316.50
ENSG00000000460        97.25        78.75
ENSG00000000938         0.75         0.00
```

Q5 (a). Create a scatter plot showing the mean of the treated samples against the mean of the control samples. Your plot should look something like the following.

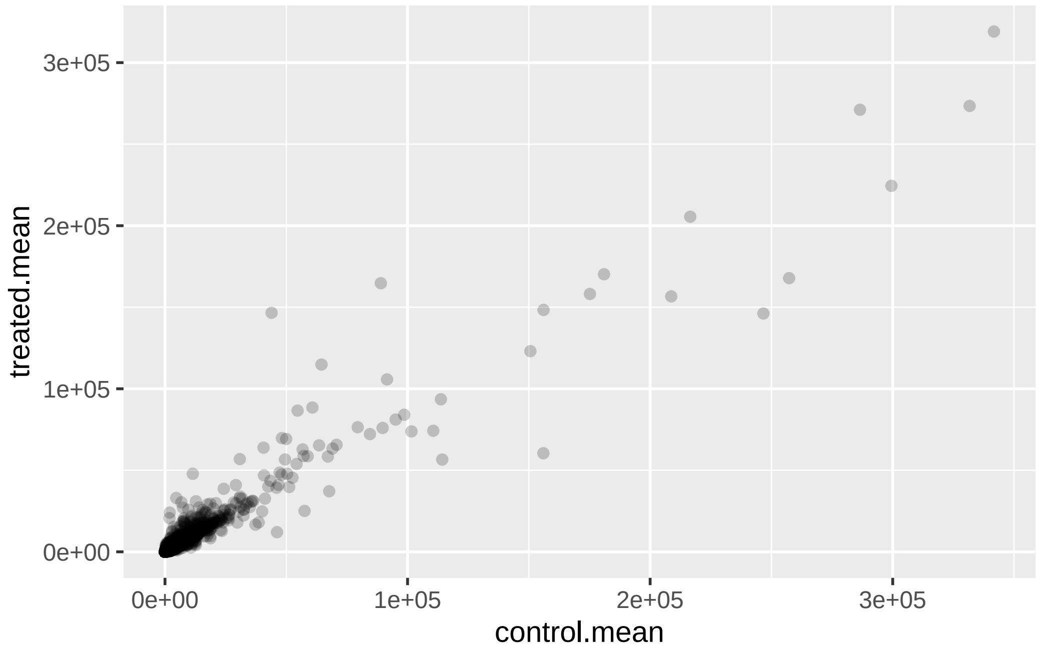
```
plot(meancounts)
```



Q5 (b).You could also use the ggplot2 package to make this figure producing the plot below. What geom_?() function would you use for this plot?

```r
library(ggplot2)

ggplot(meancounts)+
  aes(control.mean, treated.mean)+
  geom_point(alpha=0.2)
```

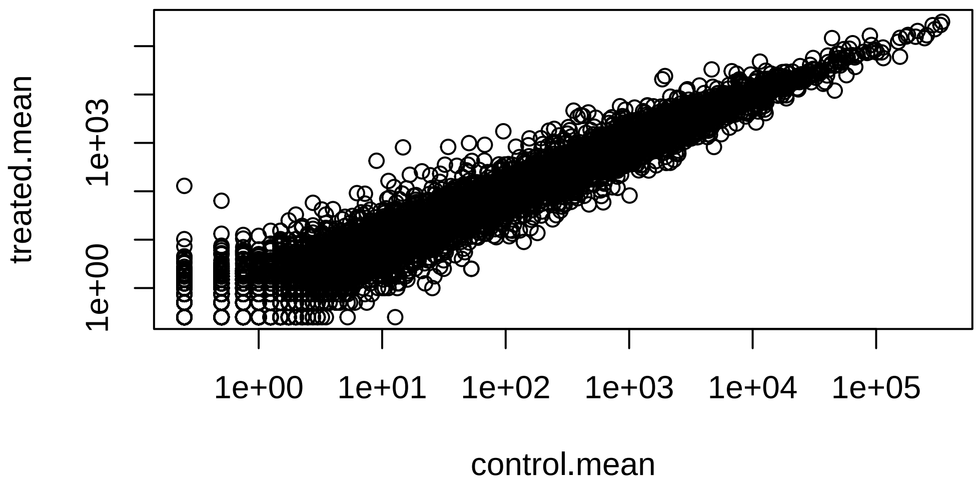


Q6. Try plotting both axes on a log scale. What is the argument to plot() that allows you to do this?

```r
plot(meancounts, log="xy")
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted
from logarithmic plot
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted
from logarithmic plot
```



Log transformations are super useful when our data is skewed and measured over a wide range like this. We can use different log transformations like base 10 or natural logs but we most often prefer log2 units.

```
#Treated/Control
log2(10/10)
```

```
[1] 0
```

what if there was a doubling

```
log2(20/10)
```

```
[1] 1
```

Half counts

```
log2(10/20)
```

```
[1] -1
```

```r
log2(40/10)
```

```
[1] 2
```

Let's add a log2 fold-change column to our little 'meancounts' data. frame:

```r
meancounts$log2fc <- log2(meancounts$treated.mean/
                          meancounts$control.mean)

head(meancounts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000005         0.00         0.00         NaN
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000938         0.75         0.00        -Inf
```

There are a couple of "weird" results. Namely, the NaN ("not a number") and -Inf (negative infinity) results.

The NaN is returned when you divide by zero and try to take the log. The -Inf is returned when you try to take the log of zero. It turns out that there are a lot of genes with zero expression. Let's filter our data to remove these genes.

```r
to.rm.inds<- rowSums( meancounts[,1:2] ==0 ) >0
mycounts <- meancounts[!to.rm.inds, ]
```

The "!" mark flips TRUE values to FALSE and vice-versa

```r
x <- c(TRUE, FALSE, TRUE)
!x
```

```
[1] FALSE  TRUE FALSE
```

> Q7. What is the purpose of the arr.ind argument in the which() function call above? Why would we then take the first column of the output and need to call the unique() function?

which() function is commonly used to find the indices of elements in a logical vector that are TRUE. which() with arr.ind = TRUE on a matrix or array, you get a matrix where each row represents the location of a TRUE element. unique() function is used to remove duplicate elements from a vector/column/matrix. Hence the arr.ind argument in which() is used to get the row and column indices of TRUE values in a matrix or array format.

On lab hand on sheet: The arr.ind=TRUE argument will clause which() to return both the row and column indices (i.e. positions) where there are TRUE values. In this case this will tell us which genes (rows) and samples (columns) have zero counts. We are going to ignore any genes that have zero counts in any sample so we just focus on the row answer. Calling unique() will ensure we don't count any row twice if it has zero entries in both samples. Ask Barry to discuss and demo this further;-)

```
x
```

```
[1]  TRUE FALSE  TRUE
```

```
which(x)
```

```
[1] 1 3
```

```
dim(mycounts)
```

```
[1] 21817     3
```

```
head(mycounts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000971      5219.00      6687.50  0.35769358
ENSG00000001036      2327.00      1785.75 -0.38194109
```

A common threshold used for calling something differentially expressed is a log2(FoldChange) of greater than 2 or less than -2.

Let's filter the dataset both ways to see how many genes are up or down-regulated.

```r
up.ind <- mycounts$log2fc > 2
down.ind <- mycounts$log2fc < (-2)
```

> Q8. Using the up.ind vector above can you determine how many up regulated genes we have at the greater than 2 fc level?

```r
sum(up.ind)
```

```
[1] 250
```

> Q9. Using the down.ind vector above can you determine how many down regulated genes we have at the greater than 2 fc level?

```r
sum(down.ind)
```

```
[1] 367
```

> Q10. Do you trust these results? Why or why not?

No I do not. The data analysis is based on fold changes. It can be large. The significance of a fold change can vary greatly depending on the context and the scale of the measurements. In some cases, even a small fold change can be biologically or practically significant, while in others, a large fold change might not be as meaningful.

On lab work sheet: For question 10, all our analysis has been done based on fold change. However, fold change can be large (e.g. »two-fold up- or down-regulation) without being statistically significant (e.g. based on p-values). We have not done anything yet to determine whether the differences we are seeing are significant. These results in their current form are likely to be very misleading. In the next section we will begin to do this properly with the help of the DESeq2 package.

#Using DESeq2

Like any package we must load up with a 'library()' call

```r
library(DESeq2)
```

```
Loading required package: S4Vectors
```

```
Loading required package: stats4
Loading required package: BiocGenerics

Attaching package: 'BiocGenerics'

Loading required package: Biobase

Welcome to Bioconductor

    Vignettes contain introductory material; view with
    'browseVignettes()'. To cite Bioconductor, see
    'citation("Biobase")', and for packages 'citation("pkgname")'.

Attaching package: 'Biobase'

The following object is masked from 'package:MatrixGenerics':

    rowMedians

The following objects are masked from 'package:matrixStats':

    anyMissing, rowMedians
```

Setup the input object requied for dds

```r
dds <- DESeqDataSetFromMatrix(countData= counts,
                              colData = metadata,
                              design= ~dex)
```

```
converting counts to integer mode
```

```
Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in
design formula are characters, converting to factors
```

Now we can run our DESeq analysis

```r
dds <-DESeq(dds)
```

```
estimating size factors
```

```
estimating dispersions
```

```
gene-wise dispersion estimates
```

```
mean-dispersion relationship
```

```
final dispersion estimates
```

```
fitting model and testing
```

Get our results back from the 'dds' object

```r
res <- results(dds)
head(res)
```

```
log2 fold change (MLE): dex treated vs control

#Adding annotation data

Our result table so far only contains the Ensembl gene IDs. However, alternative gene names and extra annotation are usually required for informative interpretation of our results. In this section we will add this necessary annotation data to our results.

```
library("AnnotationDbi")
```

```
Warning: package 'AnnotationDbi' was built under R version 4.3.2
```

```
library("org.Hs.eg.db")
```

```
columns(org.Hs.eg.db)
```

```
 [1] "ACCNUM"       "ALIAS"        "ENSEMBL"      "ENSEMBLPROT"  "ENSEMBLTRANS"
 [6] "ENTREZID"     "ENZYME"       "EVIDENCE"     "EVIDENCEALL"  "GENENAME"
[11] "GENETYPE"     "GO"           "GOALL"        "IPI"          "MAP"
[16] "OMIM"         "ONTOLOGY"     "ONTOLOGYALL"  "PATH"         "PFAM"
[21] "PMID"         "PROSITE"      "REFSEQ"       "SYMBOL"       "UCSCKG"
[26] "UNIPROT"
```

The main function we will use here is called 'mapIds'

Our current IDs are here:

```
#mapIds()
head(row.names(res))
```

```
[1] "ENSG00000000003" "ENSG00000000005" "ENSG00000000419" "ENSG00000000457"
[5] "ENSG00000000460" "ENSG00000000938"
```

There are in ENSEMABLE format. I want "SYMBOL" ids:

```
res$symbol <- mapIds(org.Hs.eg.db,
                     keys=row.names(res), # Our genenames
                     keytype="ENSEMBL",        # The format of our genenames
                     column="SYMBOL",          # The new format we want to add
                     multiVals="first")
```

```
'select()' returned 1:many mapping between keys and columns
```

```
head(res)
```

```
log2 fold change (MLE): dex treated vs control

#Pathway analysis

We will use the gage package along with pathview here to do geneset enrichmment (a.k.a pathway analysis) and figure generation respectively.

```r
library(pathview)
```

```
##############################################################################
Pathview is an open source software package distributed under GNU General
Public License version 3 (GPLv3). Details of GPLv3 is available at
http://www.gnu.org/licenses/gpl-3.0.html. Particullary, users are required to
formally cite the original Pathview paper (not just mention it) in publications
or products. For details, do citation("pathview") within R.

The pathview downloads and uses KEGG data. Non-academic uses may require a KEGG
license agreement (details at http://www.kegg.jp/kegg/legal.html).
##############################################################################
```

```r
library(gage)
```

```r
library(gageData)
```

what we need for 'gage()' is our genes in ENTREZ id format with a measure of their importance.

It wants a vector of e.g fold-changes.

```r
foldchanges <- res$log2FoldChange
head(foldchanges)
```

```
[1] -0.35070302          NA  0.20610777  0.02452695 -0.14714205 -1.73228897
```

Add ENTREZ ids as 'names()' to my 'foldchanges' vector.

```r
names(foldchanges) <- res$entrez
head(foldchanges)
```

```
       7105       64102        8813       57147       55732        2268 
-0.35070302          NA  0.20610777  0.02452695 -0.14714205 -1.73228897 
```

Now we can run 'gage()' with this input vector and the geneset we want to examine for overlap/enrichment

```r
library(pathview)
library(gage)
library(gageData)

data(kegg.sets.hs)

# Examine the first 2 pathways in this kegg set for humans
head(kegg.sets.hs, 2)
```

```
